Conventional power semiconductor devices include a semiconductor body, such as a silicon (Si) semiconductor body, having an active surface, which is an exposed surface, of a first conductivity type, such as n-type. Further, a semiconductor body may be implemented as a diode, a transistor, a thyristor, a gate turn-off thyristor (GTO), or the like. Typically, the semiconductor body has an active region with a second conductivity type formed therein. A depletion region typically exists in the active region. An electrode, such as a cathode electrode, is formed on the active surface. During device operation, a voltage is applied between the electrode and the active surface, which can forward bias the depletion region. Conventional power semiconductor devices also have a substrate disposed beneath the active surface, which

[A case of lung adenocarcinoma with multiple liver metastases, which responded well to cisplatin-based chemotherapy]. The patient was a 62-year-old man who had left pneumonectomy and multiple liver resections for lung adenocarcinoma with multiple liver metastases. He had received 5 courses of cisplatin plus gemcitabine as postoperative adjuvant chemotherapy, and there had been no sign of metastasis of the lungs and liver. He was readmitted to our department with bloody stool. Gastrointestinal endoscopy revealed a red and white nodule from the prepyloric region. Gastrointestinal lymph node metastases were suspected on computed tomography. We diagnosed the patient with progressive disease. There was no systemic metastasis in the lungs and liver. He started therapy with 3 courses of docetaxel (75 mg/m<sup>2</sup>), and in this case, this novel therapy resulted in a decrease in primary lesions.
