Modern computing devices, particularly those that are portable, have a processor with a built-in memory for storing data being processed by the processor. The memory is typically a semiconductor integrated circuit, and is referred to as the "main memory." The main memory may be volatile or non-volatile. A volatile memory is a memory that requires power to maintain its contents. For example, the main memory may be volatile dynamic random-access memory (DRAM) or pseudo DRAM. Some examples of non-volatile memory include: (1) a magnetic disk (i.e., a non-volatile disk) or a flash memory; and (2) an optical disk, where contents are read from the disk based on the reflection of a beam off of an optical disk. Additionally, some computing devices, like some cellular telephones, have a relatively large and fast main memory. For these devices, the main memory is often a non-volatile SRAM. Typically, a processor accesses the main memory via a memory controller, which is also referred to as a memory bus controller. Memory accesses from the memory controller to the main memory typically involve one of two types of accesses: (1) a page-based access, where the access is in pages—i.e., multiple consecutive address locations that are grouped together for simultaneous access from the memory controller; and (2) a 55cdc1ed1c
